Real Input Real Output

Let us consider the dataset given below

What would be the prediction for decision tree with depth 0?

Prediction for decision tree with depth 0. Horizontal dashed line shows the predicted Y value. It is the average of Y values of all datapoints.

What would be the decision tree with depth 1?

Decision tree with depth 1

The Decision Boundary

What would be the decision tree with depth 2?

Decision tree with depth 2

The Decision Boundary

Here, Feature is denoted by X and Label by Y. Let the "decision boundary" or "split" be at X = S. Let the region X < S, be region R₁. Let the region X > S, be region R₂.

```
Here, Feature is denoted by X and Label by Y.
Let the "decision boundary" or "split" be at X = S.
Let the region X < S, be region R<sub>1</sub>.
Let the region X > S, be region R<sub>2</sub>.
```

```
Then, let

C_1 = \text{Mean} (Y_i | X_i \in R_1)

C_2 = \text{Mean} (Y_i | X_i \in R_2)
```

Here, Feature is denoted by X and Label by Y. Let the "decision boundary" or "split" be at X = S. Let the region X < S, be region R₁. Let the region X > S, be region R₂.

```
Then, let

C_1 = \text{Mean}(Y_i | X_i \in R_1)

C_2 = \text{Mean}(Y_i | X_i \in R_2)

\text{Loss} = \sum_i ((Y_i - C_1 | X_i \in R_1)^2 + (Y_i - C_2 | X_i \in R_2)^2)
```

Objective function

Here, Feature is denoted by X and Label by Y. Let the "decision boundary" or "split" be at X = S. Let the region X < S, be region R₁. Let the region X > S, be region R₂.

Then, let

$$C_1 = \text{Mean}(Y_i | X_i \in R_1)$$

 $C_2 = \text{Mean}(Y_i | X_i \in R_2)$
 $\text{Loss} = \sum_i ((Y_i - C_1 | X_i \in R_1)^2 + (Y_i - C_2 | X_i \in R_2)^2)$

Our objective is to minimize the loss and find $\min_{S} \sum_{i} ((Y_i - C_1 | X_i \in R_1)^2 + (Y_i - C_2 | X_i \in R_2)^2)$

How to find optimal split "S"?

1. Sort all datapoints (X,Y) in increasing order of X.

- 1. Sort all datapoints (X,Y) in increasing order of X.
- 2. Evaluate the loss function for all

$$S = \frac{X_i + X_{i+1}}{2}$$

and the select the S with minimum loss.

Draw a regression tree for Y = sin(X), $0 \le X \le 2\pi$

Dataset of Y = sin(X), $0 \le X \le 7$ with 10,000 points

Regression tree of depth 1

Decision Boundary

Regression tree with no depth limit is too big to fit in a slide. It has of depth 20. The decision boundaries are in figure below.

- Interpretability an important goal
- Decision trees: well known interpretable models
- Learning optimal tree is hard
- Greedy approach:
- Recursively split to maximize "performance gain"
- Issues:
 - Can overfit easily!
 - Empirically not as powerful as other methods

What would be the decision boundary of a decision tree classifier?

Decision Boundary for a tree with depth 1

(b) Decision Tree

Decision Boundary for a tree with no depth limit

(c) Decision Boundary

(d) Decision Tree

As we saw, deeper trees learn more complex decision boundaries.

As we saw, deeper trees learn more complex decision boundaries.

But, sometimes this can lead to poor generalization

An example

Consider the dataset below

(e) Train Set

Underfitting

Underfitting is also known as *high bias*, since it has a very biased incorrect assumption.

(g) Decision Boundary

(h) Decision Tree

Overfitting

Overfitting is also known as *high variance*, since very small changes in data can lead to very different models. Decision tree learned has depth of 10.

Intution for Variance

A small change in data can lead to very different models.

Dataset 1

Dataset 2

Intution for Variance

A Good Fit

As depth increases, train accuracy improves

As depth increases, train accuracy improves As depth increases, test accuracy improves till a point

As depth increases, train accuracy improves As depth increases, test accuracy improves till a point At very high depths, test accuracy is not good (overfitting).

Accuracy vs Depth Curve : Underfitting

The highlighted region is the underfitting region. Model is too simple (less depth) to learn from the data.

Accuracy vs Depth Curve : Overfitting

The highlighted region is the overfitting region. Model is complex (high depth) and hence also learns the anomalies in data.

The highlighted region is the good fit region. We want to maximize test accuracy while being in this region.

How to find the optimal depth for a decision tree?

How to find the optimal depth for a decision tree?

Use cross-validation!

Our General Training Flow

K-Fold cross-validation: Utilise full dataset for testing

FOLD 1	Train			Test
FOLD 2	Train		Test	Train
FOLD 3	Train	Test	Train	
FOLD 4	Test	Train		

The Validation Set

Nested Cross Validation

Divide your training set into *K* equal parts.

Cyclically use 1 part as "validation set" and the rest for training. Here K = 4

Average out the validation accuracy across all the folds Use the model with highest validation accuracy

- How to combine various models?
- Why to combine multiple models?
- How can we reduce bias?
- How can we reduce variance?
